Abstract

The evolution of novel traits can involve many mutations scattered throughout the genome. Detecting and validating such a suite of alleles, particularly if they arose long ago, remains a key challenge in evolutionary genetics. Here we dissect an evolutionary trade-off of unprecedented genetic complexity between long-diverged species. When cultured in 1% glucose medium supplemented with galactose, *Saccharomyces cerevisiae*, but not *S. bayanus* or other *Saccharomyces* species, delayed commitment to galactose metabolism until glucose was exhausted. Promoters of seven galactose (GAL) metabolic genes from *S. cerevisiae*, when introduced together into *S. bayanus*, largely recapitulated the delay phenotype in 1% glucose-galactose medium, and most had partial effects when tested in isolation. Variation in GAL coding regions also contributed to the delay when tested individually in 1% glucose-galactose medium. When combined, *S. cerevisiae* GAL coding regions gave rise to profound growth defects in the *S. bayanus* background. In medium containing 2.5% glucose supplemented with galactose, wild-type *S. cerevisiae* repressed GAL gene expression and had a robust growth advantage relative to *S. bayanus*; transgenesis of *S. cerevisiae* GAL promoter alleles or GAL coding regions was sufficient for partial reconstruction of these phenotypes. *S. cerevisiae* GAL genes thus encode a regulatory program of slow induction and avid repression, and a fitness detriment during the glucose-galactose transition but a benefit when glucose is in excess. Together, these results make clear that genetic mapping of complex phenotypes is within reach, even in deeply diverged species.
