Molecular Details of the Mutation

"The greyish Gr^{1/4}enochte goat carried one copy of the Apc allele, which causes the characteristic black and white pattern of Swiss Peacock goats (Henkel et al. 2019). The Apc allele consists of a central quadruplication of ~45 kb with triplicated adjacent flanking regions comprising ~28 kb and ~42 kb, respectively."

Abstract

The Valais Blackneck goat is a Swiss goat breed with a characteristic coat color phenotype. Before the revision of the breed standard in 1938, 4 different color varieties of Valais goats were known. Besides Blackneck animals resembling the modern breed standard, the brown and white Copperneck goat, the white Capra Sempione, and the greyish Gr^{1/4}enochte comprised the historic Valais goats. The brown pigmentation of Copperneck goats had previously been traced back to an introgression of a mutant TYRP1 allele from Toggenburg goats. In the present study, we identified additional introgression events of distinct ASIP alleles causing the remaining 2 rare coat color patterns within the Valais Blackneck goat breed. We identified the introgression of the AWt allele from Appenzell or Saanen goats in white Capra Sempione goats. Similarly, introgression of the Apc allele from Peacock goats resulted in the greyish Gr^{1/4}enochte phenotype. These results demonstrate past hybridization events between breeds that are separated today. A perfect genotype-phenotype association in 393 Valais goats supported the causality of the genotyped variants for the different coat color phenotypes. Our study gives insights into the introgression of functionally relevant copy number variant (CNV) alleles controlling pigmentation between goat breeds with strikingly different coat color patterns.

COMMENTS

@Introgression The duplicated region also contains two other genes AHCY and ITCH, which do not appear to be involved in pigmentation: AHCY is an enzyme involved in L-homocysteine biosynthesis and ITCH is an E3 ubiquitin-protein ligase.
