Abstract

In the Republic of Korea (ROK), six sibling species of the *Anopheles sinensis* complex are considered the vector species of malaria, but data on their susceptibilities to malaria and vector capacities have been controversial. The intensive use of insecticides has contributed to the rapid development and spread of insecticide resistance in the *An. sinensis* complex. Knockdown resistance (kdr) to pyrethroids and DDT in the *An. sinensis* complex is associated with a mutation in codon 1014 of the voltage-gated sodium channel (VGSC) gene. Because the degree of insecticide resistance varies among mosquito species and populations, the detection of kdr mutations among the six sibling species of the *An. sinensis* complex is a prerequisite for establishing effective long-term vector control strategies in the ROK. Because of the difficulties with species identifications that are based only on morphological characteristics, molecular identification methods have been conducted on every specimen. Part of the IIS6 domain of the VGSC was polymerase chain reaction-amplified and directly sequenced.

The molecular analyses revealed that mutations existed at codon 1014 only in *An. sinensis* sensu stricto and no mutations were found in the other five *Anopheles* species. In *An. sinensis* s.s., one wild type (TTG L1014) and three mutant types (TTT L1014F, TTC L1014F, and TGT L1014C) of kdr alleles were detected. The TTC L1014F mutation was observed for the first time in this species.

The fact that the highly polymorphic kdr gene is only observed in *An. sinensis* s.s., out of the six *Anopheles* species and their geographical distribution suggest the need for future studies of insecticide resistance monitoring and investigations of species-specific resistance mechanisms in order to build successful malaria vector control programmes in the ROK.
